and posteriorly; legs ochreous, anterior and middle tibiae and tarsi and posterior tarsi fuscous marked. Forewings brownish fuscous, with three dorsal outwardly-oblique white streaks widened at base and margined with a few black scales, somewhat cursed apically, the third one nearly connected with a white slender outwardly-oblique black-margined line at three-fourths of costa, beyond this white line three or four white costal spots: a round black spot at apex with a few pale bluish scales, a few pale bluish scales between this spot and the third dorsal white streak, sometimes this area ochreous: apical and terminal cilia brownish, paler near base and black at extreme base, tornal cilia very pale brown. Hindwings and cilia pale brown. Abdomen pale brownish. Expanse of wings, $7.5-8 \mathrm{~mm}$.

Resembles epibathra Walsm. and hibiscella Sw., but a smaller species, the gromd color of forewings darker, and slight differences in apical markings. Described from 6 specimens reared from mines in leares of Teraudia melastomatofo.

ILar. Two specimens Punalun, Oahn, Jme 11, 1916, and $t$ specimens Waiahole, Oahu, August 13, 1916 (Swezey). A serics of five specimens reared from leares of Pipturus albidus at Pahoa, Puna, Hawaii, September 20. 1918 (Swezey) seems to be the same species. Termudin and Pipturus are near related trees. and it is not mulikely that the same species might attack both plants, tho of three species of Philodoria mining Pipturus leaves. not one of them has yet been found mining Neraudia leares.

## Miscellaneous Notes on Hymenoptera, 2nd Paper, With Descriptions of New Species.

## BY .TOHN GOLBURN BRITITELI.

 sthateaxis and Other Duxg Fhy Ladiae.

Among the parasites of dung flies secmed by Mr. A. Koehele in Germany and Sivitzerland in his search for parasites of the hornfly and sent to Honoluln for liberation, was a series of Bathymetis which the literature at hand does not permit us to identify. Specimens in the collection of the

Proc. Haw. Entom. Soc., IV, No. 2. June, 1920.

Hawaiian Sugar Planters' Asociation show that it was bred from material sent in 1905. 1909, and 1911.

Mr. Swezey (Planters’ Record 2: :360-366, 1910) recordhreeding it from some lots of material receired October 15. 1909. Some parasites had already emerged and died, twelve were still living and twenty more emerged during the following week and a new generation was secured, and by November, eight adults of a new gencration were secured from dipterous puparia in cow dung, the parasite oripositing in the puparia. Subsequent sendings received from (oct. 28 to $\mathrm{J}_{\text {an- }}$ 7. 1910, prodnced about tis parasites and from these and the parasites secured hy breeding, colonies of 20 females and 20 males were liberated in Manna Valley (Nos. 190s) : 21 females and 39 males in Ňuanm Valley (Nor. 1909) ; 26; females and Bt males at Waalae Dairy: 26 females and ist mates (Nor. 1909) and ahout 12 femates and 30 mak, (May. 1910) also on Oahn, the exact locality not designated. and on Mani, at the Grove Rameh, 11 females and 17 mates (Jan. 1910) : and a colone of 16 females and ?t males were sent to the Parker Ranch on Mawaii for liberation (Dere. 1909). Mr. Swezey also records (op. (Cit. 7:2:s, 1912) rereiving a shipment from Switzrlant on Nor. 29. 1911, from which 14 females and 30 males emerged dnring the next 1 wo monthe of which some were liberated.

He found that with the advent of the winter seavon with its slight reduction of temperature wost of the parasites went into a hihernating condition on reaching full larval growth. some keeping dormant in this way from December motil May.

It is interesting to note that there is a single male of this species in the collection referred to, bred out Jannary 4 . 1912. from a puparium brought down from Manoa Valley he Mr. Muir. I canmot find that the species has been seen since. It does not seem that the species comld in any ease prose rery important in the control of the horntly since it attacks the purariom and this in the horn tly is tightly enrewed in the hardened dong so that the parasite womld hawe
great difticulty in penetrating to it, its oripositor being too short to penetrate to any great distance. It is also not in any way a special enemy of the hornfly but apparently attacks any muscoid puparia it encounters.

## 26. Aspilota konae Ashmead.

This species has been taken in recent years on Oahn only in the mountains; on M[t. Kaala, in Wailupe, Palolo, Waimano and Opaeula valleys by Srezey, and from Mt. Kaala, Palolo and Kulionou by Timberlake.

In Jamary or February, 1914, the tree shells of the genus Achatinella were found down on the paths along the Castle trail in large numbers and from them were bred the Sarcophagid Dyscritomyia sp. From one of the puparia of this fly 5 or ${ }^{6}$ Alysiids were lored. In the press of other work at the time this material was probably all lost, but I am inclined to believe that it was this speries which emerged. In any ease it has so far always been taken in the regions where these flies are found. It would not be surprising if it should prove to lo an endemic species.

The variation in the nmmber of antennal joints in the species is most remarkable. I have seen females with 26 joints and others with lout is while the type was deseribed as having 28 joints.

## 27. Tabie of Some Species of Halfaitan Braconidal.

With the exception of one or two species, the Bracomidae found in the Hawaiian Islands are immigrant forms brought in ly ordinary operations of commerce or, in some instances, purposely introduced in the effort to control obmoxious insects. In all about forty species are now known to be established and it is desirable for the use of local workers to have the species tabulated. The writer has recently tabulated* the species falling into the sub-family long known as the Braconinae lut which through the vicissitudes of type

[^0]fixation have required a new group name. For this group Gahan has propoed the name Vipinate**. This name apparently cannot stand. In the first place the genitive of lipio is Tipionis, and the sulfamily wathe lased on it is correctly Vipioninae which the writer used in the phare referred to. But the name of the genus which is the type of the sulfamily is now Microbracon and the sulpfamily should then he called the Mierobraconinae.

The Braconidae tabulated here have been placed in various subfamilies but to the writer they seem to belong together. However, in defanlt of opportumity for thomgh consideration of the matter he does not wish to give them at present any common designation.

They have the following characters in common: the head is completely margined behind and there is a sinns lowtween the elypens and the mandibles. In all but the wingles: endemic Ecphylopsis nigra Ashmead the parapsidal furrows are strongly impressed, there are two closed cubital cells in the front wing and in the hind wing there are two cross veins extending backward from the mediellan rein, a nervellus near the middle of the mediellan ceell and a postnervellme interstitial with the baselns. All the species so far as their habits are known are parasites of beetle larvae and all of these but Heterospilus prosopidis, the Bruchus parasite, attack wool-boring beetles. The habits of the endemic Erphylopsis are unknown.

## TABLE OF SPECIES.

r. Wingless, a very small mountain species. I. Eicphylopsis migra. Winged species
2. Abdomen petiolate or sulpetiolate, the first tergite much longer
 Alxlomen not petiolate, first tergite with the sides converging in front, its posterior margin but little if at all shorter than a side

[^1]3. Vhrlomen distinctly petiolate, the first tergite subcylindrical, hind femora simple. not toothed----------2.Spathius perdebilis Perkins Abdomen with the first tergite flattened, but little narrower than the third, hind femora incrassate and toothed beneath.
3. Euscclinus peregrinus Perkins
4. First tergite abont one and one half times as broad as long, abdomen oval, hind wings of male with psendostigma.
4. Heterospilus prosopidis Viereck

First tergite not broader than long, abdomen more elongate, hind wings without a pseudostigna_
5. Subdiscoidal nervure continuing in the same line with the discoidal, abdomen with transverse row of crenulate sulci on tergites
3-5---------------------------------. Hormiopteruts ìggrans 11. sp. Subrliscoidal nervure arising from the interbrachial nervure, abdomen without transverse row of crenulate sulci except on tergite three
6. Female and male pale testacenus, thorax and abdomen often much infuscate but the parapsidal furrows always pale, third tergite without a cremulate furrow.
6. Ischiogonus palliatus (Blackburn)

Female with the head pale, thorax and abdomen black. male pale testaceons, third tergite with a crenulate furrow.
7. Ischiogonus pallidiceps Perkins

## 28. A New Lmmiornit Hommopeteres.

## Hormiopterus vagrans 11. sp.

Female: Head brownish-yellow, eyes black, mandibles and antennae infuscate toward apex; thorax and abdomen dull reddish brown, propoderm and first tergite black, the other tergites more or less dark on the disk; legs pale testaceous, the tarsi a little infuscate at apex; ovipositor sheaths black apically: paler at base: wings subhyaline, iridescent, the nervures blackish, paler apically, stigma and costa except at apex pale testaccons.

Antennae about 35 -jointed, abont as long as the entire body, all the joints longer than broad. first flagellar joint a little longer than the second; face thinly hirsute, funely gramular, with shallow indefinite punctures; eyes rounded, cxceedingly slightly emarginate opposite the antemac, malar space broad; genae a little broader below; ocelli in a very small triangle, separated from each other by but little more than the diameter of one, much nearer to each other than to the eye margin; front, vertex, and occiput minutely tessellate; oceiput and vertex with the hairs directed forward.

Mcsonotum roughly tessellate or gramular, hirsute, the parapsidal furrows converging behind and meeting at abont two-thirds of the distance to the scutellum and continued to it in a broad shallow rugulose
furrow with three longitudinal carinae: sides oi pronotum rugulose with a longitudinal carina near the middle reaching to the front and hind margins; mesopleura and mesosternum margined in front, a deep smooth furrow on either side separating the stermum from the pleura, the vertical furrow broal and rugose, mesopleura tessellate granulate above, smooth below and shining as is the sterntm, middle line of mesosternum crenulate; prescutellar sulcus not deeply impressed, divided by about five raised longitudinal lines; propodeum with two well defined lateral areas touching in front and each bounded by a raised consute line, the rugose petiolar area therefore narrowed.

Abdomen slightly longer than head and thorax combined, widest across the fourth segment, the ovipositor about two-thirds as long; pedicel about as long as its apical width and longitudinally, coarsely rugoso-striate; second tergite short, transverse and closely fused with the third, its apical margin broadly raised and polished, its broad margin more narrowly raised and smooth, between is a transverse row of longitudinal sulci and coarse striae; third and fourth tergites each with it transverse row of crenulate sulci at the basal margin, the striae separating the sulci radiating obliquely outward especially towards the sides of the disk and gradually becoming obliterated before reaching the apical margin, which is smooth, the striae sometimes branching or more often with secondary fimer striae in the interstices but these generally do not reach quite to the basal margin; fifth tergite similar to the preceding two but the striae are wholly longitudinal and parallel; second to fifth tergites moreover become rugoso-striate on the vertical sides and slightly more finely sculptured here than on the disk: sixth tergite minutely tessellate at base and fimely, transversely lineolate at apex: last two tergites mostly concealed beneath the sixth and apmarently wholly smooth.

Length, 3.6; wing, 2.8; oripositor, I.I mm.
Male: Similar to the female, but the abdomen is much -lenderer, the second tergite no shorter than the following segments: each of the first five tergites, including the pedicel, with coarse striae reaching nearly to the apex of the segments, the interstices rugose with fine cross lines; antennae with about 27 to 29 joints.

Length. 2.6; wing, 2.3 mm .
Weseribed from 16 femates, 11 males realred from lamean

 Momolulu, on Mt. Tantalıs, and in Palolo, Nin, Wralupe,
 Timberlake), the earliest specinen having been taken in Nius.

Trepe and allotype in the eolleretion of the Itamaian En-
tomological Society. Paratypes in the collection of the Hawaiian Sugar Planters' Association, and in the collections of Mr. Timberlake and the author.

2!. Oftpostrson of Ischiogonets pallatus (Blackbirn).
A lot of three females and males were bred from a larra of Plagithmysus pulverulentus under the bark of Acaciu tioa from Oahn brought in by Mr. Swezey. These emerged about June 15, and were fed and seen to mate and were placed with a branch of Euphorbia containing larvae of Neoclytarlus and on July 7 four males and three females had emerged. These were placed with material coutaining larvae of Neoclytarlus. A female was seen ovipositing July S, the oviposition leing similar to that of Meterospilus prosopidis, the oripositor being grasped by the apical two-thirds of the sheaths, the bases of the sheaths and oripositor being widely separated. The sheaths are strongly hent and served to brace the oripositor while in operation. The oriposition was nearly complete when noticed and no details further were observed.

This species has been recorded by Dr. Perkins as attacking the Plagithmysine beetles in the native forests. My, ohservations show that these attacks are remomsible for a very heary mortality among them, particularly in the ease of species attacking thin-barked trees.

## 30. Myrmosula Bradley.

Nyrmosa purma Fox and $M$. rufiventris Blake were originally included. The former may be considered the type. Probably the group is hetter considered as generic.

Myrmosula rufiventris (Blake).
This speries has apparently been represented in collections by the mique type in the collection of the American Entomological Society from Nevada.

It is represented in the anthor's collection by a single
male collected at Corvallis, Oregon, June 30, probably 1907 or $S$ (J. C. Bridwell).

This has since remained in my collection midentified. the peenliar structure of the mandibles haring been mudeseribed. The mandibles are rather elongate and slender and lidentate at apex, the lower tooth being much longer than the upper. When the mandibles are closed, doubtless the luge median tooth is concealed. This is sub-triangular. a little recurved, acute at apes, and a little !onger than its distance from the upper (or inner) apical tooth.

In Myrmosa unicolor the mandible is tridentate at the apex and the inner hroad triangular tooth is much mearer the apex of the mandible.

## 31. Odinerus pseubochromus Perkins.

Occasionally this species has the angles of the propodeum reddish and a large romed spot on either side of the seeond tergite.

The male varies also with elypeus with an encireling vellow margin as well as the red spots on the seeond tergite. Either of these variations may exist independent of the other.

Pseudochromus may be distinguished from leiodemas lyy the smooth lateral area on the dorsal face of the propodemm. This species emplors the propal chambers of Anobiid heetles from whieh the beetles have emerged as well as the pith cavities of the twigs. In either case the ravity contaning the cells is closed by a mud plug at the entrance some distance away from the last cell. Two or three cells fill the Amohiid pupal chamber while I have seen nests of a dozen cells in pith carities.

## 32. Two New Nearctic Species of Mypomiscopluts Cockerell from the Pioffic Coast.

Hypomiscophus Cockerell and Miscophinus Aslmead are synonymons and were published upon the same day. Prof.

Cockerell has apparently shown that his genus was published a few hours earlier and his name is accordingly used here.

Hypomiscophus aenescens n . sp.
Male: Length 4.25 mm .; wing 3 mm .
Black; face, front, and vertex, and thorax with dull bronzy reflections; mandibles rufopiceous apically, flavotestaceous basally as is the anterior margin of the clypens; legs with the incisures and the hind tarsi obscurely testaceous; wings sulhyaline, iridescent, apically infuscated; the nervures brownish except costa which is blackish. Face to front, occiput, and margins of tergites with conspicuons appressed pubescence appearing silvery in certain lights, elsewhere there generally lies conspicuous fine appressed pubescence. Clypeus with the middle lobe truncate apically, convex on the disk, not carinate; front with a feeble impressed line reaching two-thirds the distance from the antemal sockets to the anterior ocelli. Eyes convergent above; ocelli in an acute triangle, anterior ocellus larger, posterior ocelli a little nearer the eye-margin than to each other.

Pronotum about as long as the mesoscutum, its sculpture microscopically wrinkled longitudinally in front, transversely behind: the mesonotal sculpture is granulo-punctate; mesopleura similar; scutellum and metanotum similar: propoderm finely transersely striolate, the median longitudinal raised line distinct; sides of propodeum longitudinally striolate: the posterior face with a triangular fovea above, on either side of which are three or four strong short parallel transverse ridges.

Abdomen with the tergites tessellate; apices of sternites 2-6 with a few erect spines.

Hind and middle tibiae with a few black spinules; nervulus inserted nearly its length before the basal nervure.

Described from a single male with the antemae mising taken at Pamelia Lake on Mt. Jefferson, Oregon, July 1f, 1917 (Bridwell). Type in author's collection.

Evidently related to nigrescens Rohwer, but the propodemm appears from the description to be much more strongly striolate in aenescens as well as the head and thorax heing brenzr in aenescens and black in migrescens.

## Hypomiscophus timberlakei n. sp.

Female: Length 6.75 mm .; wing, 4 mm .
Black: scape piceous apically; tegulae black, piceous apically; mandibles obscurely flavotestaceous, rufopiceons at apex; abdomen ferruginous apically and the basal segment more blackish; tarsi dull reddish;
wings hyaline iridescent, infusate apieally: venation brownish. Face and occiput and apices of tergites with some appressed silvery pubescence with some less conspicuous fine smilar short hairs elsewhere generally:

Anterior margin of middle lobe feebly rounded ont, impressed in the middle and slightly emarginate, the disk convex: front with a short, faintly impressed median line nearly midway between the antemal sockets and the anterior ocellus. Eyes rather strongly convergent above, ocelli in an acute triangle, the hind ocelli distinctly nearer the eye margin than to each other and nearer each other than to the occipital margin, three times the width of an ocellus in front of the summit of the eyes.

Front, vertex, pronotum, mesonotum, mesopleura, scutellum and metanotum appearing finely granular under a hand lens, really very closely minutely punctulate, propodemm very fincly transversely obliquely striolate, the longitudinal raised line obscure, placed in a shallow groove, the sides olliquely longitudinally striolate, the posterior face with a triangular fovea above, with short transverse ridges on either side similar to those in acnescons but more numerous; abdomen tessellate.

Anterior tibiae with a comb composed of a few elongate setae: posterior and middle tibiae with a few spines. Sternites $2-5$ with a few erect black setae on the margins.

Nervulus interstitial with the basal nervure. 1oirst joint of flagellum a little longer than second.

Deseribed from two females collected at lowhild. Mt. San Jacinto, California, July, 1912, the type collected by P. II. Timberlake for whom the opecies is namert, and the ather be the writer.

Trye in the author's mollection.
Two other species are described as having the abdomen more or less ferruginous. II. aremumb (ookerell is a smaller species ( 3 mm.), the tiliae are red and the longitudinal raised line of the propoderm is distinet. If. Icxomus (Ashmead) hats the legs entirely red, the petiole of the 2 nd cubital cell is doseribed as only a third as long as the side of the coll while in timberlake it is more than half as long. Texamus is a smallor species ( 3 mm .) and the propodeal raised longitudinal line is distinct, the eollar is said to be brownish ferruginoms and the two or thee apieal ecoments are said to be dark. These .lifferemeers may be inconstant, sine in the two individuals of
timbertaki before me, one has the apical segment black and the other is dark only at the apex.

33. A Neh Niteline (iencs from Soeth Africa.

## Mutillonitela new genus.

Head transverse, oblong, the eyes clongate, convergent above occupying the entire side of the head from the vertex to the base of the mandible. Mandibles edentate, strongly notched before the middle. Clypens transverse, broadly expanded in front, entire along the whole margin, with about six strong flattened blunt parallel spines beneath the margin in the middle. Antemnae inserted just above the clypens, the sockets in a line with the anterior margin of the eyes, scape stont and excavated at apex. Ocelli in an obtuse triangle, the hind ocelli in front of the summit of the eyes. A deep fovea between the ocelli and eye margin, wings somewhat abbreviated with completely closed costal, median, submedian, one cubital, one discoidal, and brachial cell. Radial cell very short, variably open at apex or closed, barely extending beyond the apex of the short first cubital cell, nervulus inserted before the basal, nervellus far before the margin of the radiclus.

Hind and middle tibiae spinose, the anterior tibiae of female with a well developed tarsal comb.

Abdomen of female without a defined pygidial aren.
Head and thorax clothed with two kinds of pulesecence. peculiar erect setae and the ordinary fine pubescence. Wings strongly pubescent, sublyaline to beyond the venation then strongly infuscate.

Related to Saliostethus and Miscophoides of Brauns but differs, hy the venation.

Type: Mutillonitela mimica Bridwell.

## Mutillonitela mimica $n$. sp

Femate: Length 5 mm .; wing 3 mm . more or less.
Black: legs, venter of abdomen and apical tergite dull ferruginous, the abdominal color darker; posterior margin of scutellum, mentanotum and outer half of wing base whitish; anterior calcar pale; middle (1) and hind (2) calcaria black; mandibles yellowish ferruginous at base, piceous apically: antemae brownish: venation of wing yellowish.

Face, front, vertex, pronotum and mesonotum with stout erect yellow1sh setae. mingled on the head and thorax above with finer silvery pile: coarse silvery hairs on mesopleura, propodemm, epipleura of tergite one. sternite two on the sides and margins of tergites and sternites.

Head, pronotum, mesonotum, scutellum, mesopleura and metanotum opaque and granular.

Collar about twice as broad as long, rounded down to the declivity; propodeum without a well defined basal area, the superior face with a
feeble longitudinal raised line in a shallow ill detined furrow, surface coarsely tessellate, with feeble radiating striolac basally and transverse ones apically, sides of propodemm obliquely striolate, posterior face narrow, with a shallow furrow and impressed line above, transwersely strongly striolate throughout: middle and hind tibiae with stont white spines on the outer face as long as the width of the tibiae; front tarsi grooved beneath, the comb strongly developed; hind and middle tarsi strongly spinose.

Abdomen with the tergites not contracted at the sutures, very fincly strongly punctate. the punctures separated by about two or three times their diameter.

Described from two females collectent at the Mowbray Golf Links, Kappenberg, near Capetown, Felo, 1915 (Bridwell). Type in the South African Mnsemm, paratype in the anthor's collection.

## Mutillonitela lounsburyi n. sp.

Female: Similar to mimica, Length 5 mun..; wing 3 mm .
Clypeus pale, ferruginous, legs brownish piceous: sentellum and metanotum black; tergites I-3 rufescent: apical two-thirds of tergite 6 whitish yellow; sternites 2-6 dark; pubescence of head much feebler and sparser: the setae reduced to pointed hairs.

Pronotum longer, punctate, the surface between more transversely rugulose; mesonotum similar: selutllum with the punctures very dintinct, well separated: mesopleura shining. the punctures irregularly disposed: propoleum similar to that of mimica but the surface more rugose: sides of propodeum shiming with strong, well separated punctures, the posterior face like that of mimica.

Abdomen shorter, more compact, first tergite broader, the punctures larger, stronger, and more separated.

Described from one femate collereted in the same loceality as mimica Fels-April, 1915 (Bridwell).

Type in the anthor's collertion.
Both species were taken rmming along the hare samd and resemble closely the small dutillidue which are fombl there mutil disturbed when they eseape by flying. I atm disposed to consider this a real ease of mimicry. A Nyssonid not bet studied was found under the same riremonstances and even more elosely resembling the $\begin{aligned} & \text { Intillidae. }\end{aligned}$

the entomological service of Sonth $\Lambda$ frica, who extended me many conrtesies during my stay in South Africa.

8t. A New Shaox from the Hawahan Lelands with Descriptions of two otileks from ('aliforia.

Silaon rohweri n . sp.
Female: Length 4.5 mm . wing 3.5 mm .
Black; mandibles piceous at apex; transverse spots on either side of collar, apex of tubercles, small spots on tegulae, small spot on either side of metanotum, oval spot posteriorly at apex of front and middle tihiae, interrupted stripe on dorsal surface of hind tibiae not attaining base or apex, and calcaria yellowish-white; wings dusky subhyaline, strongly iridescent, venation dark brown.

Rody with fine silvery pile covering the surface on the sides of the clypens and sides of face.

Mandibles simple, clypens produced in the middle and rounded with a rounded median longitudinal ridge continued as a fine carina to about the middle of the eyes, disappearing at the protuberance of the front: front vaguely and indefimitely impressed longitudinally in front of the anterior ocellus; eyes somewhat convergent above; ocelli in an obtuse triangle, the posterior ones in front of a line connecting the summit of the eyes. nearer to the eye margin than to each other; process and median ridge of clypens smonth and shining, a few coarse punctures

on the edge of the pubescence which conceals the sides; front and vertex strongly confluently punctured, the genae and occiput more fincly so.

Collar not margined or carinate anteriorly; mesonotum, scutellum, and mesopleura closely and subconfluently punctate; basal margin of
propodenm consute: superior face with irregular transerse well separated fine rugac; the surface between tensellate; with an imperfectly defined triangular basal area extending over on the declivity; posterior face transversely rugose or striate divided by the longitudinal sulcus: sides of propodeum fincly longitudinally striate.

Tergites very fincly but strongly punctate the interspaces, two or three times as wide as a puncture; first, second, and third tergites with margins depressed, more narrowly laterally; the depression of second and third is not quite one-third the length of the tergite. Sternite shining, more coarsely punctured, the margins testaceous.

Nervulus nearly interstitial, first recurrent received by the first cubital cell.

Male: Similar to female but the hind tarsi with the first and second joints pale.

The clypens produced into a narrowly rommed tonth. The last joint of antenne longer than broad about as long as the three preceding joints. Next to last and preceding joint shorter above than below. Basal area of propodeum more definitely finely rugostriate, the striae radiating from the central furrow. Seventh sternite entirely concealed, cighth produced in the middle into a broad. flat truncate process a little longer than broad and about $1-3$ the width of the sclerite.

Described from a single femalo sperimen secmed by swecping at Walanae village, ()ahn, att seat level, May 2?, 191! (bridwell), and a mak fiom Ewa ('oral l'lan bred from a cooron in the borings of Neorlytartus enphorbine.

It is mot absolntely certam that this is an immigrant speries, sinco several endemio llymenopera orent in the locality where it was found. It is, howerer, pobable that it is introduced through commerce, possibly from Central America or Mexico.

Named in honor of Mr. S. A. Rohwer, who has described a majority of the North Smerican species.

Some dead Euphorbia wood eontainime the boringe of Neoclytartus euphorbiae Bridwell was taken at Sisal on the Ewa Coral Jlain on August S1, 1919. The examination of two pieces of the main stem of a bush, probably from the samm hush, revealed fom cells comstructed hy this wasp. Earh cell
 ing throngh which the athlt heetle hat emereed was phegent "p with hits of coral, mand amd regetable debris, in one in-
stance some small dried leaves of the Euphorbia were used, in :mother the glumes of a grass. Apparently the mud is placed without much order within the chamber and there is no definite coll wall surromnding the prey and larva of the Silaon.

In two of the cells the larva had died and the dried up prey remained. This consisted of the nymphs of the Lygacid bng, $N$ ysius, helonging to an motermined species. One contained 12 nymphs and a small dried up larva of the Silaom. But one of the nymphs had been fed upon. The other contained a larger dried up larva and four nymphs, two of which had heen fed upon somewhat.

The other two cells contained a cocoon of the Silaom. These eocoons are nearly elliptical in outline with one end a little larger than the other. The eocoon is earthy, commingled with a little silk and sand grains. They are about 2 mm . thick by : mm. long.

The nesting place is similar to that described by Xambean for s. sambeani Andre and the eocoon resembles that of that species. S. compeditus of Enrope was found by Eerton burrowing in the gromed and making a series of cells containing nymphe of Lygacid, while Williams fond siluon inerme (Cresson) in Kansas storing Capsid (Mirid) nymphs in a hole in the gromd apparently in a spider's honrow.

Since the description above was written Dr. F. X. Willians has taken additional material from the Ewa Coral Plain and ohserved the habits of the species in the ficld. I ann greatly obliged to him for the opportmity to include this material in the type series: (ifemales, ! males taken at Sisal, March and April, 1920.

Type and allotype in the collection of the Hawaiian Entomological Socicty. Paratypes in the collection of the Hawaiian Sugar Planters' Association, and in the private collections of Dr. Willians and the anthor.

Through the kinduess of Dr. Williams I am permitted to use the arcompanving figure of the female which is his work.

## Silaon blaisdelli n. sn.

Female: l.ength 3.5 mm .: wing 2.5 mm .
Nervulus interstitial with the basal nervure, first recurrent norvure received by the first cubital cell.

Black; mandibles more or less piceous at apex; interrupted line on collar, tubercles, spot on tuhercles, tegulae, spot on apex of front and middle tibiae behind, stripe on tibiae outwardly, calcaria, and stripe on metanotum yellowish-white; margins of tergites and sternites pale testaceons. Body with appressed silvery pubescence, more conspicuous on sides of face, and on the margins of the tergites laterally Clypens shining not carinate, produced into a short rounded process in the middle, front below with a tectiform ridge: gibbosity of front not impressed; eyes but little divergent below; ocelli in an obtuse triangle: the posterior ocelli in front of the summit of the eyes, about one half as far from the eye margin as from each other.

Face, front, vertex, occiput, collar, mesoscutum, scutellum and metanotum finely, closely and distinctly punctate, the metanotum more finely so: mesopleura with the surface sculpture similar in general but amewhat concealed by the pubescence, above the impressed pit on the mesepimeron is an ill-defined, glabrous shining spot with the surface microscopically tessellate. Propodeum with the basal area well defined by a U-shaped raised line, basally are some weak radiating striae not one-fourth the length of the area, apically the rugosity of the surface is transverse: sides of propodeum finely longitudinally striolate: fovea of posterior face shallow, the parallel transverse ridges feeble but numerous and reaching well toward the sides.

Wings subhyaline, iridescent, the venation brownish. The petiole of the second cubital cell short, not more than a fourth the length of the sides of the cell, the cell triangular.

Abdomen shining, finely, discretely punctate.
Described from a single female rollected at San Diego, California. March 2!, 1s!1 (Dr. F. E. Blaisdell). Type in the anthor's rollection.

Similar to rohweri. From rohweri it differs be the welldefined propodeal area and longer propodem. The basal area is I'shaped in rohweri. Parrus (of which the female is undeseribed) is deseribed as having the radial eell not appendicoulate while it is distinctly on in blaistelli. The hasal area of the propoderm of purtus is deseribed as triangular while it is distinctly rommed behind in baisdelli. Otherwise from the deseription the species are very near each other.

## Silaon similis n. sp.

Length: 6.5 mm . wing +mm .
Nervulus inserted distinctly beyond the basal (about the width of the vein), first cubital cell receiving both recurrents.

Black; transverse spot on either side of collar, tubercles, narrow apical line at apex of trochanters behind and spot on the middle of hind tibiae behind yellowish-white; calcaria whitish; mandibles piceous at apex: tegulae, tarsi, and margins of abdominal segments brownish; wings subhyaline, nervures yellowish except costa and stigma, blackish.

Appressed silvery pubescence very conspicuous on clypeus and face, less so on cheeks, collar, mesopleura, sides of propodeum and base and apex of tergites (interrupted medially), continued along the sides of the abdomen. Middle tibiae with a few whitish spimules. sternites 2-5 with the usual erect whitish setae on the margins.

Clypeus strongly carinate, the apical margin of the middle lobe thickened and shining, subtrumeate, a little rounded out: eyes strongiy convergent above: carina extending from the clypeus over the front, unt strong. connecting a little above the antennal sockets with an impressed line which deepens into a shining forea on the middle of the front and is continued faintly to the anterior ocellus. Front rather strongly, coarsely and closely punctured, becoming striate in the depression in front of the large front ocellus, vertex longitudinally striate between the ocelli, smooth and shining obliquely in front of the hind ocelli with a few fine ptunctures on the orbits there; the head behind the ocelli and the occiput transersely striatopunctate; ocelli in an equilateral triangle, the hind ocelli a little nearer the eye-margin than to each other and further than this from the occipital margin.

Pronotum very short, a little notched in the middle abruptly declivous in a plane in front but not carinate. Mesonotum closely, coarsely subconfluently punctured, the parapsidal and median lines indicated but not impressed; mesopleura without an impressed pit. more discretely punctured on its disk: scutellum strongly discretely punctured more sparsely on the disk: metanotum very fincly and closely punctured; propodeum with the basal area ill-defined, bare, opaque. with a few radiating wrinkles more distinct at base and an imperfect raised line, the general surface subreticulate, with smooth shallow punctures in the interspaces; the basolateral areas with the surface concealed by pubescence: sides of propodeum glabrous shining, obliquely striolate, posterior face transversely striate, the fovea rather shallow.

Abdomen shining, the first tergite strongly finely rather deeply punctate, the others more finely and less distinctly so: sternites similar.

Closely related to $S$. plenoculoides (Fox) lont the middle tibiae have some spimules, and the details of the head and propodeal sculpture seem different. Rohwer describes the pro-
